14. ABSTRACT					
This report describes an Android application for facilitating exchange between English-speaking and Dari-speaking domain experts with the help of mobile devices such as smartphones and tablet computers. The U.S. Army Research Army Laboratory (ARL) has been developing English-to-Dari phrasebooks in a variety of specialized domains (medical, legal, financial, et al.). This application provides bi-directional English-Dari text translation using a dictionary of medical phrases selected and translated from the English-language medical training manual, <i>Fundamental Critical Care Support (FCCS)</i> , published by the Society for Critical Care Medicine (SCCM). The application is database-driven and is domain agnostic and easily adaptable to other specialized domains.

## Acknowledgments

---

The content for this Medical Phrasebook Application is an extensive set of technical medical terms extracted from translated texts. To automate the identification of technical terms, the ARL project team made use of the U.S. National Library of Medicine's Unified Medical Language System (UMLS), which includes knowledge sources and advanced tools useful for the development of computer systems that behave as if they understand biomedical language.

We would also like to acknowledge the use of a freely available package called com.ahmadiv.dari.DariGlyphUtils from <http://code.google.com/p/glyph-util/>

Android 2.2 does not display Persian/Arabic letters correctly. This package has been used to connect and reshape Persian/Arabic letters for correct display and legibility.

**INTENTIONALLY LEFT BLANK.**

---

## **1. Introduction**

---

The U.S. Army Research Laboratory's (ARL) Computational and Information Science Directorate (CISD) has been developing translation technologies and translation tools to support security transition operations in Afghanistan. U.S. Soldiers serving on medical Embedded Training Teams working with the medical units of the Afghan National Army have pointed the need to accelerate the transfer of modern medical knowledge to medical schools, physicians and other medical professionals in Afghanistan. High quality translations of medical training texts are urgently needed, but difficult to produce in a country where the educational infrastructure is rebuilding after decades of conflict.

In the course of a project to produce a special trainer's edition of a medical reference manual, the need for a bilingual English-Dari glossary of technical medical terms became very apparent as the project team sought to achieve clarity and consistency across all chapters and appendices of the book. Software designed to help automate the selection of technical terms was pressed into service and a sizeable collection of more than 6,000 English words and phrases peculiar the medical training, each with its Dari equivalent, was the result.

Developed primarily as input for training translation software, the English-Dari medical glossary contains information that is immediately useful for trainers, students, physicians and other medical professionals. While printed paper copies might be one way to share this information, a software version of an English-to-Dari and Dari-to-English Medical Phrasebook offers a number of important advantages, including ease of use and portability. Given the great popularity of cellular phones in Afghanistan and throughout the developing world, a Medical Phrasebook application for the Android operating system presented itself as a very practical means of proliferating and sharing this medical knowledge.

This paper documents the development of an application for a bidirectional English-Dari Medical Phrasebook based on critical care medical terms. Designed for Google's Android platform, it allows data entry and look-up in both languages, making use of either a soft keyboard or a device's hardware according to user preference. The paper first describes the development environment, then moves to the design of the application with a discussion of the rationale behind key design decisions. Finally, we provide the documented source code for the application itself.

---

## **2. Development Environment**

---

Google's Android is an open-source software stack intended for mobile devices such as cell phones and tablets. The development environment consists of a Software Development Kit (SDK) written for the Java programming language, and a series of tools integrated with the Eclipse integrated development environment (IDE) for development and debugging. The Android SDK and the associated tools are freely available from Google at <http://developer.android.com>. The version we used for this development was SDK Tools Revision 10 with the Android Development Tools (ADT) Eclipse Plug-in for Eclipse Helios. The target platform was Android 2.2. The Motorola Droid 2 was the phone used for testing.

Additionally, Android 2.2 does not natively support a Persian keyboard or the shaping of Dari characters.\* A package freely available from <http://code.google.com/p/glyph-util/> called com.ahmadiv.dari.DariGlyphUtils was used to reshape the Dari phrases.

---

\* Persian languages are cursive instead of block lettering so the characters must be joined or “shaped”.

---

### 3. Application Design

---

Figure 1 illustrates the overall class diagram for the application.

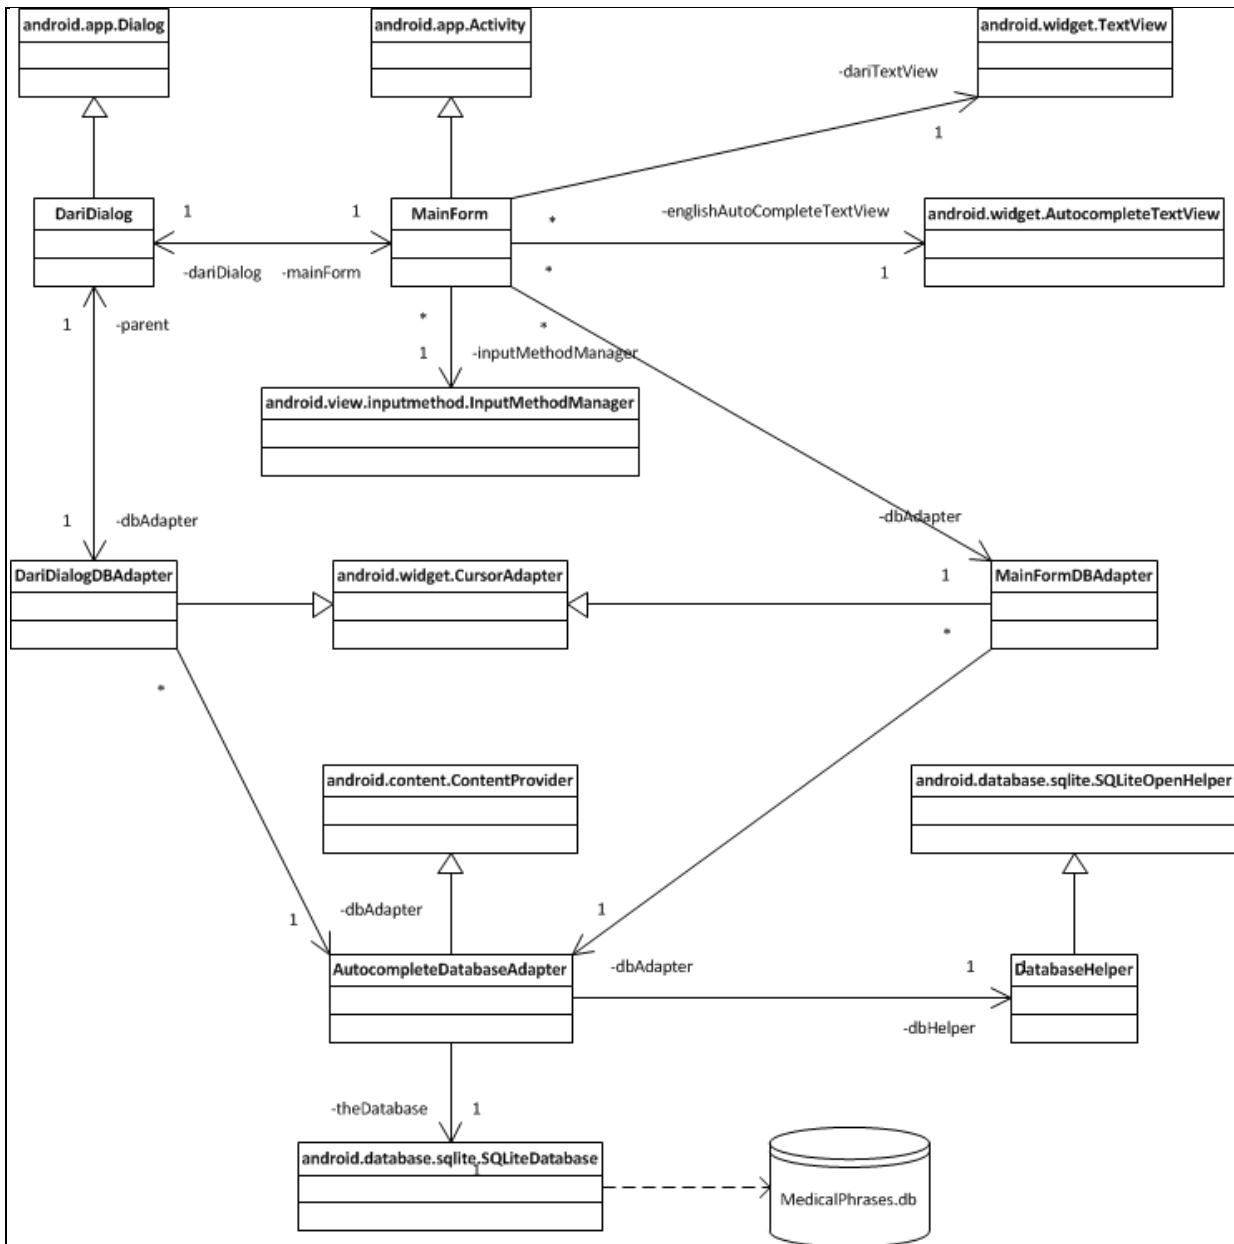

Figure 1. English-Dari medical phrasebook class diagram.

### 3.1 The Look and Feel

MainForm is the Android Activity<sup>†</sup> that presents the user interface (UI) for the English-Dari Medical Phrasebook. MainForm presents the UI through a number of widgets organized in an Android layout. The widgets and layout are specified in an XML file called main.xml, which lives in the layout folder under the application's resource folder (called res). Our MainForm uses a Linear Layout nested inside a Relative Layout for the entry screen. The UI for our main entry screen annotated with the widgets and layouts is shown in figure 2, and the main.xml is listed in the appendix.

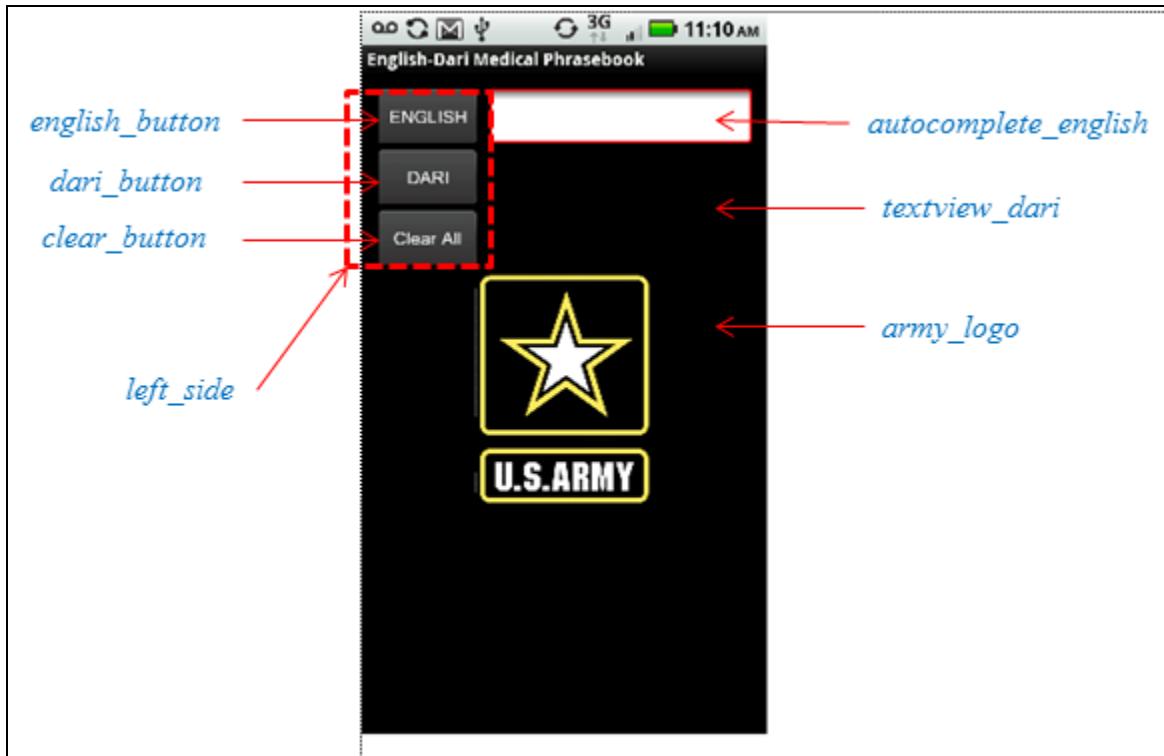

Figure 2. MainForm screenshot.

The MainForm's top-level layout is an Android RelativeLayout. A RelativeLayout allows child widgets and other views to specify their position relative to each or their parent. The buttons are contained within the *left\_side* Android LinearLayout. A LinearLayout aligns the children in either a vertical or horizontal direction. In this case, we set the orientation to vertical and force the child buttons to be set to the same width and height (`android:layout_weight = "1"`). The *english\_button* is used to initiate translations from English to Dari. The *dari\_button* is used to initiate translations from Dari to English. The *clear\_button* clears both the *english\_button* and the *dari\_button* to prepare for a new translation. The *autocomplete\_english* widget is an Android

<sup>†</sup>“An Android Activity is a single, focused thing that the user can do. Almost all activities interact with the user, so the Activity class takes care of creating a window for you in which you can place your UI with `setContentView(View)`.” (<http://developer.android.com/reference/android/app/Activity.html>) The application's main activity is typically the entry screen.

AutoCompleteTextView, which shows completion suggestions from the list of English medical phrases after the user has typed in at least three characters (`android:completionThreshold = "3"`). It is used to specify the input phrase for an English-Dari translation and display the result of a Dari-English translation. The `textview_dari` widget is an Android TextView that is set to be uneditable (`android:editable = "false"`). It is used to display the result of an English-Dari translation and to capture the input from the custom Dari soft keyboard (described later) used to specify the input for a Dari-English translation.

### 3.2 English-Dari Translation

An English-Dari translation is initiated by either pressing the `english_button` or clicking in the `autocomplete_english` text view. Either action will bring up the Android's native soft keyboard as illustrated in figure 3. Once the user has entered at least three characters that match the beginning of an English medical phrase in the database, a list of potential matching phrases drops down beneath the `autocomplete_english` widget as shown in figure 4. Once at least three characters have been entered into the `autocomplete_english` AutocompleteTextView, it calls `runQueryOnBackgroundThread` on a MainFormDBAdapter with the characters entered so far. The MainFormDBAdapter is an Android CursorAdapter used to bind the ListView associated with the drop-down suggestion list for `autocomplete_english` with a database cursor. The MainFormDBAdapter then calls an AutocompleteDatabaseAdapter with the partial English phrase. The AutocompleteDatabaseAdapter is an Android ContentProvider, which in this case encapsulates the SQLite database containing the English and Dari medical phrases. The AutocompleteDatabaseAdapter issues an SQL query of the form “`SELECT english, dari FROM phrase WHERE english LIKE partialPhrase%`”. If the query returns a non-empty result set, the AutoCompleteDatabaseAdapter calls the Android Activity (in this case the MainForm) to `startManagingCursor`, which results in a drop-down list of suggestions appearing below the `autocomplete_english` AutoCompleteTextView. Once the user has clicked on a suggestion, the `onItemClick` method of the `autocomplete_english` is invoked. The `onItemClick` method then asks for the English phrase from the database cursor and sets its text to the corresponding string. It then retrieves the corresponding Dari phrase from the same cursor, calls the DariGlyphUtils to reshape the Dari string, and then uses that to set the text on the `dari_textview` widget. Once the translation has been retrieved, the drop-down disappears, the English phrase is captured in the `autocomplete_english` text view, and the Dari translation is captured in the `textview_dari` text view as shown in figure 5. This comprises one iteration of an English-to-Dari translation. The UML Sequence Diagram for this use case is shown in figure 6.

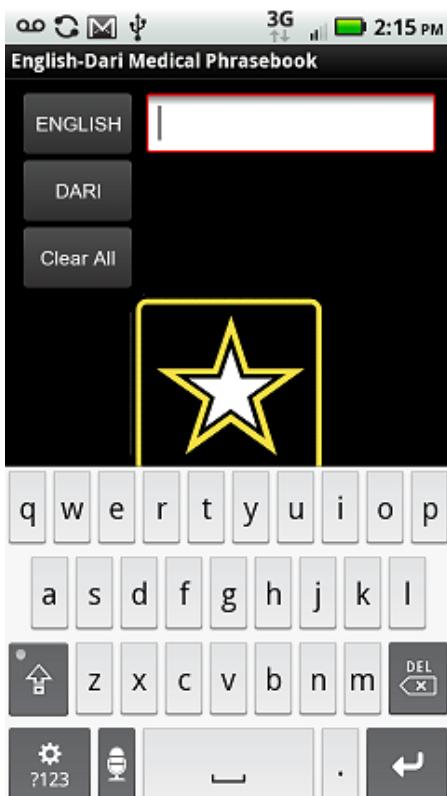

Figure 3. Start of an English-Dari translation.

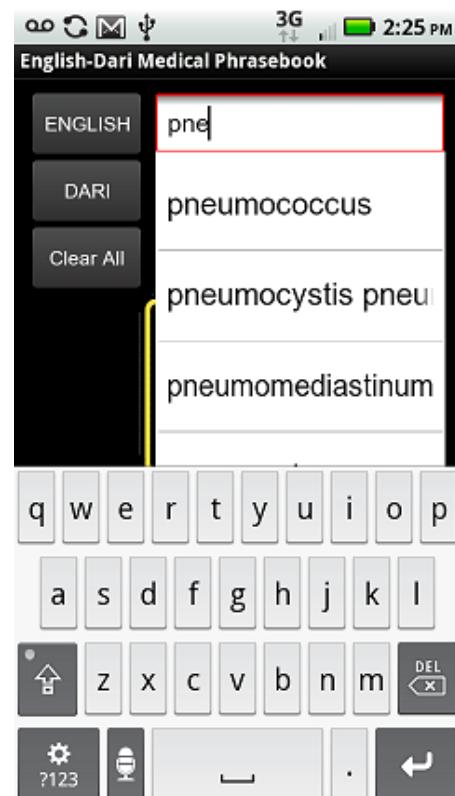

Figure 4. Autocomplete suggestions.

Figure 5. Completed English-Dari translation.

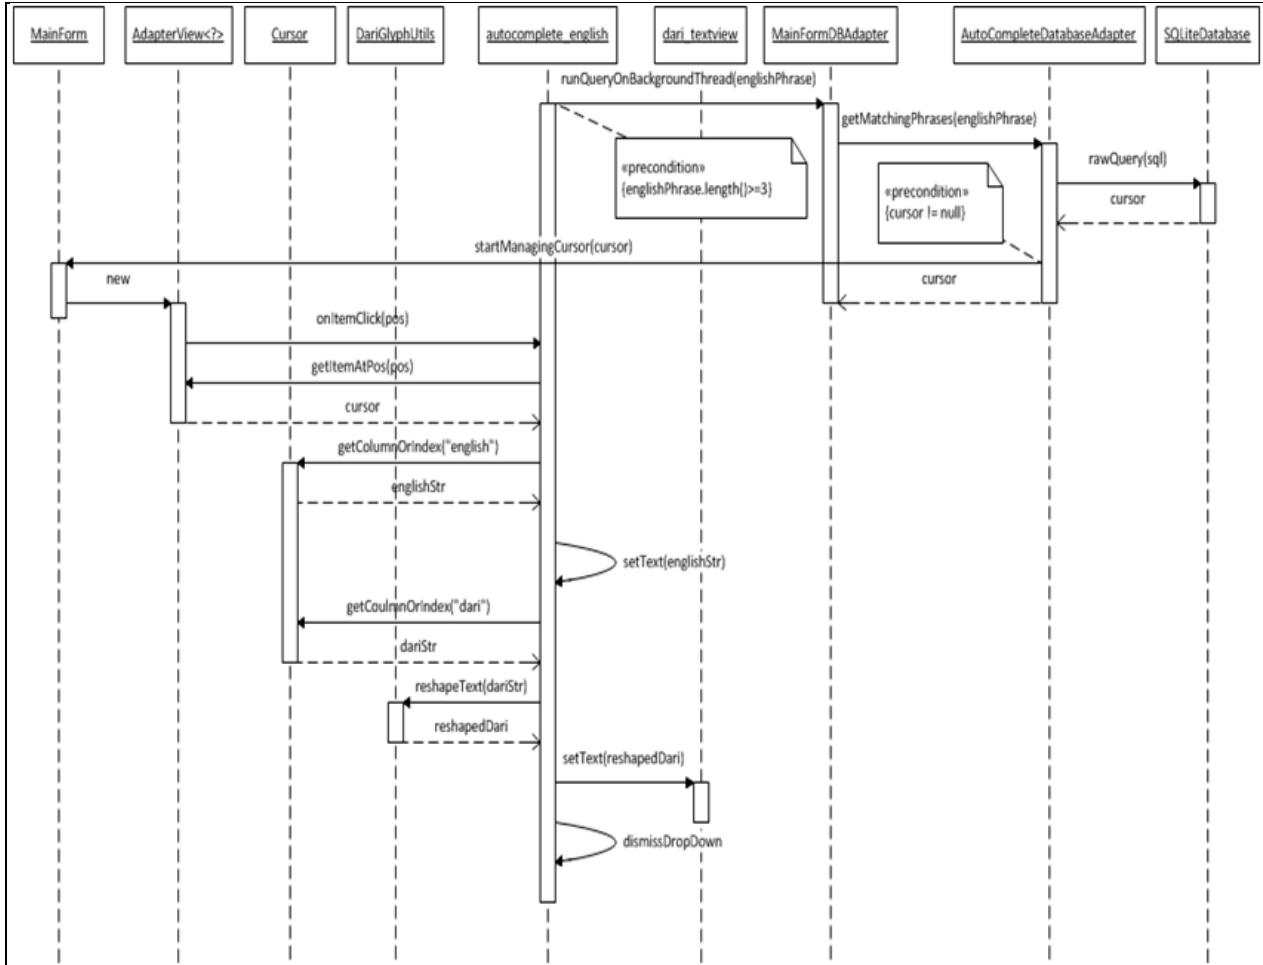

Figure 6. English to Dari sequence diagram.

### 3.3 Dari-English Translation

Translation of medical phrases from Dari into English is initiated by clicking the *dari\_button*. Dari-English translation is complicated by the lack of native support for Persian languages in Android 2.2. Third-party Persian soft keyboards are available, but due to platform limitations the user must manually go into the device’s settings to switch between languages. Since manually switching keyboards during a single translation is an unacceptable burden on the user, this required the creation of a custom soft keyboard for the Dari character set. The design of this keyboard is discussed in a later section.

Clicking on the *dari\_button* will bring up the custom soft Dari keyboard as illustrated in figure 7. Once the user has entered at least three characters that match the beginning of a Dari medical phrase in the database, a list of potential matching phrases drops down beneath the *autocomplete\_dari* widget in the Dari Keyboard as shown in figure 8. Once at least three characters have been entered into the *autocomplete\_dari* AutocompleteTextView, the database is queried to display potential matching phrases in a similar manner to that described for the

English-Dari translation. Once a Dari phrase has been selected the database is queried (again in a similar manner as that described for the English-Dari translation) to find the matching English phrase. Once the translation has been retrieved, the Dari soft keyboard and drop-down disappear, the Dari phrase is captured in the *dari\_textview* text view, and the English translation is captured in the *autocomplete\_english* text view, as shown in figure 9. This comprises one iteration of a Dari-to-English translation. The UML Sequence Diagram for this use case is shown in figure 10.

Figure 7. Dari soft keyboard – vertical layout. Figure 8. Autocomplete Dari suggestions.

Figure 9. Completed Dari-English translation.

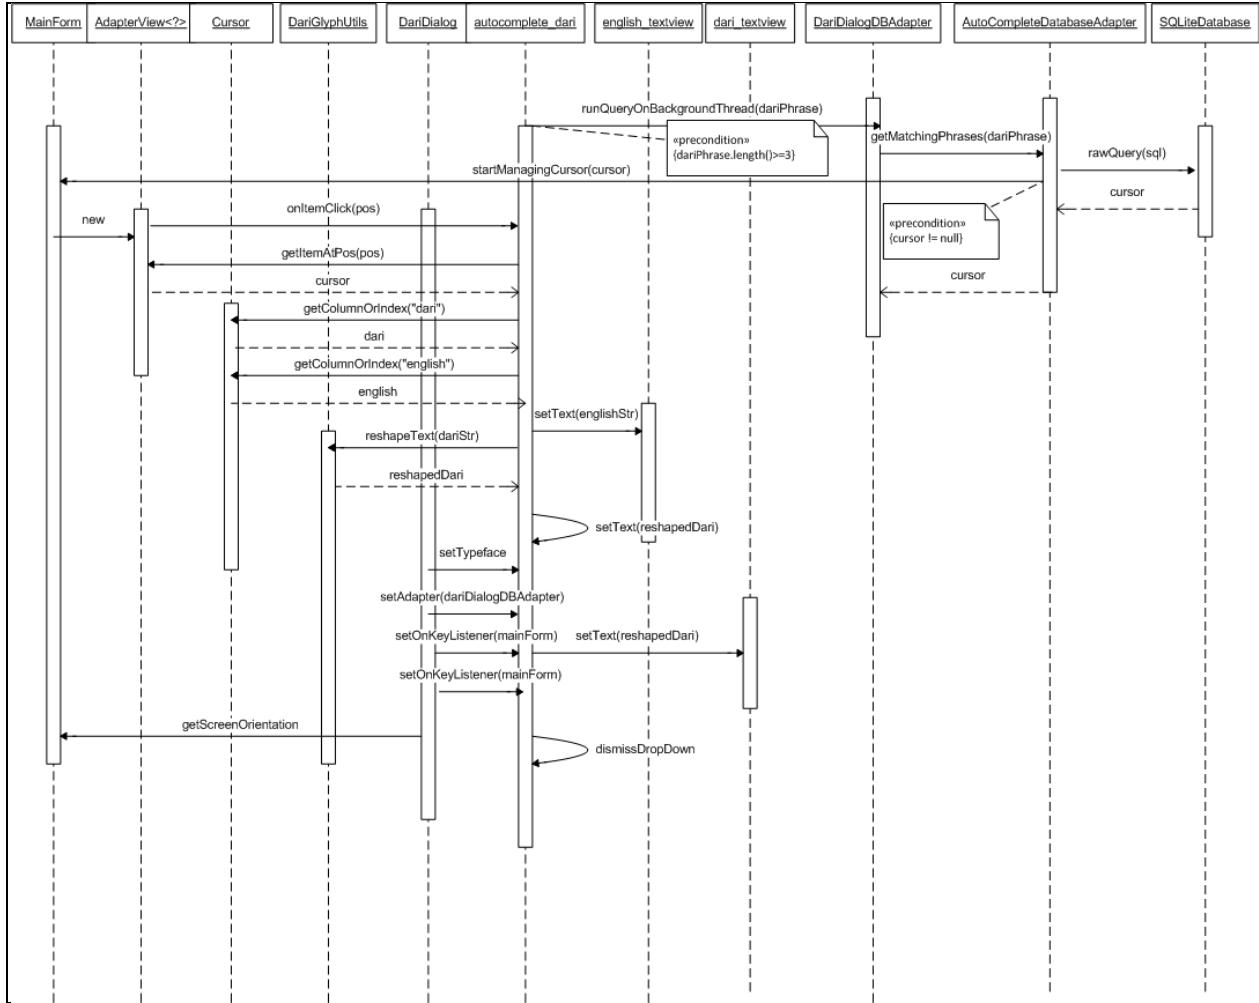

Figure 10. Dari to English sequence diagram.

### 3.4 The Dari Soft Keyboard Design

If a hard keyboard exists on the device, we would like the Dari soft keyboard to have a natural, intuitive mapping to the hard keyboard. Complicating the design of the Dari soft keyboard was the fact that 32 characters are used instead of the 26 used in English. We implemented two different layouts for the Dari soft keyboard using the following assumptions. If the device is held in a vertical orientation, then any hard keyboard associated with the device will typically not be available, and it is unnecessary to accommodate a natural, intuitive mapping to the hard keyboard layout. On the other hand, if the device is held in a horizontal orientation, then the hard keyboard is likely to be accessible, and a different layout that tries to mimic the hard keyboard layout in a natural and intuitive way should be preferred. Figure 7 shows the Dari soft keyboard in the vertical orientation. Figures 11 and 12 show the layout in the horizontal orientation. Since Dari uses six more characters than English, the shift key was employed to introduce the additional characters. The positioning and mapping of the characters to keys was copied from existing Dari keyboard layouts designed for desktop computers. When the shift key is off, the top

row on the Dari soft keyboard maps to the top row of letters on the QWERTY keyboard. The second row on the Dari keyboard maps to the middle row of letters row on the QWERTY keyboard. And the third row on the Dari keyboard maps to the bottom row on the QWERTY keyboard. When the shift key is on, the Dari characters displayed are mapped to the ‘W’, ‘T’, ‘I’, ‘S’, ‘G’, and ‘Z’ keys, mimicking the layout on Dari keyboards designed for desktop PCs. Since it is often difficult to tell exactly which key is being pressed on soft keyboards, one additional feature we wanted to mimic from the native soft keyboard was to temporarily pop up a displaced and enlarged view of the key being pressed. We used an Android Toast for this purpose. Figure 13 illustrates this in action of the Dari soft keyboard.

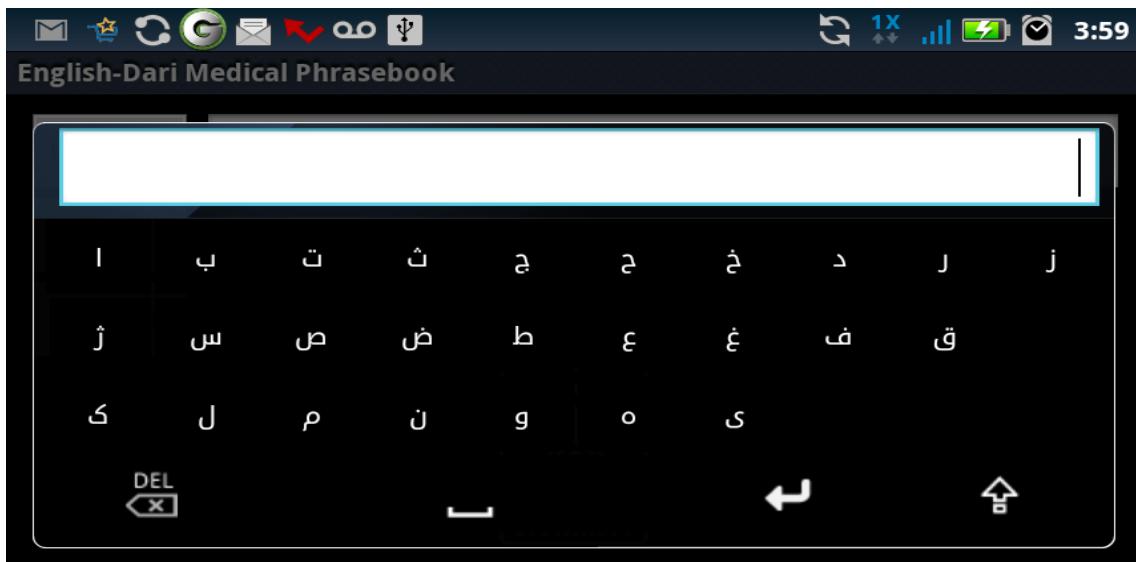

Figure 11. Dari soft keyboard - horizontal layout (Shift OFF).

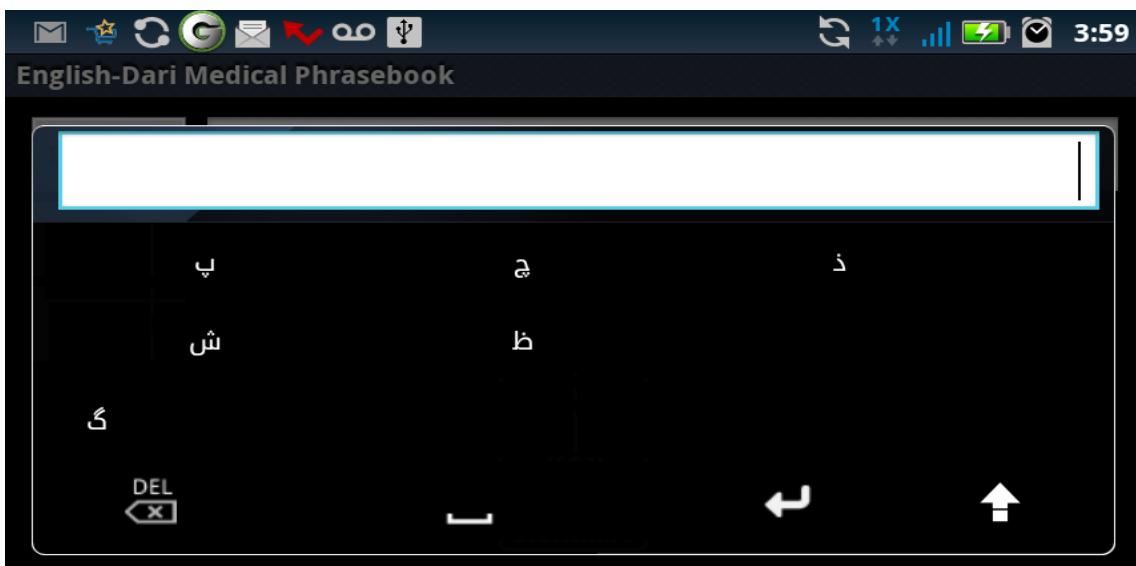

Figure 12. Dari soft keyboard – horizontal layout (Shift ON).

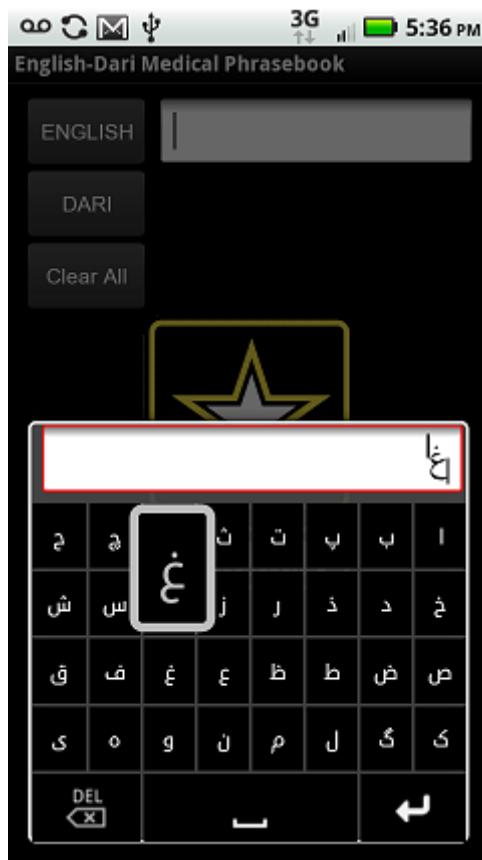

Figure 13. Dari keyboard with toast.

### 3.5 Porting of the Application to Android 3.0 (Honeycomb)

The English Dari phrasebook application has been ported to Android 3.0 Honeycomb. This version of the Android operating system supports larger screens like those found on tablets. With Honeycomb, the tablets do not need physical buttons/hard keyboard; the soft keyboard buttons appear on the bottom of the screen regardless of which way the device is oriented. This eliminates the need of intuitive mapping of Dari soft keyboard to the hard keyboard. Figure 14 shows the look and feel of Soft Dari keyboard when displayed on a tablet. Figure 15 shows the native soft English keyboard.

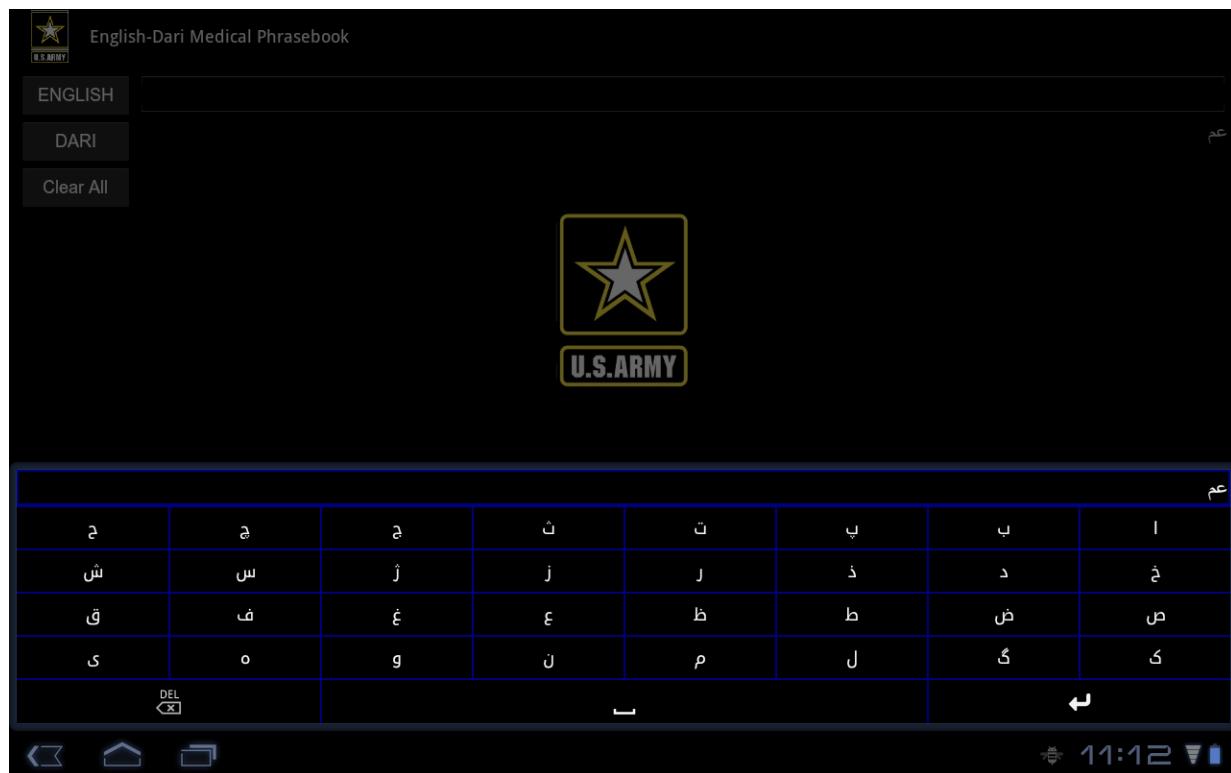

Figure 14. English Dari medical phrasebook on Android 3.0 Honeycomb (Soft Dari keyboard displayed).

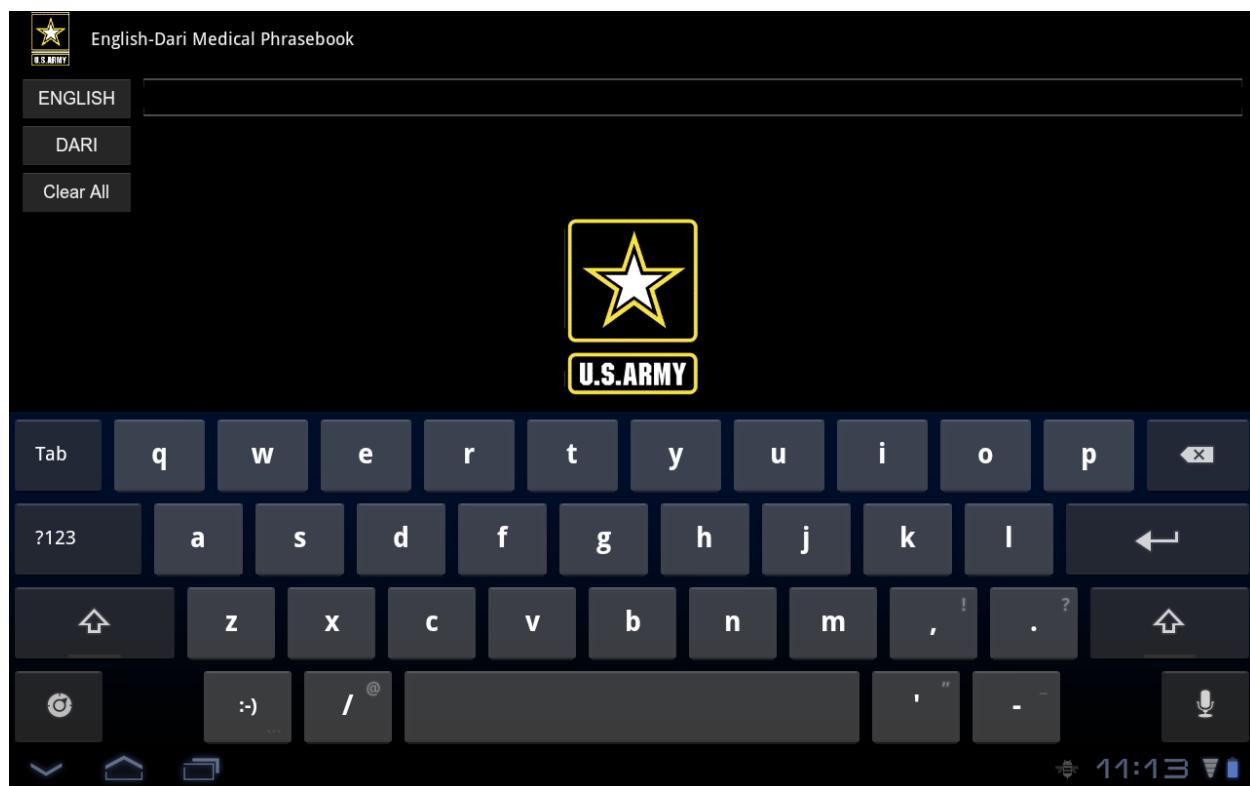

Figure 15. English Dari medical phrasebook on Android 3.0 Honeycomb (Soft English keyboard displayed).

---

## **4. Conclusion and Future Work**

---

We have presented the design and implementation of an Android application for the translation of a vetted, manually translated suite of some 6,000 English medical phrases from *Fundamental Critical Care Support (FCCS)*, published by the Society for Critical Care Medicine (SCCM), to Dari and from Dari back into English. The application is database-driven, meaning that new domains can be added or substituted by merely changing or replacing the database. Additionally, we are in the process of collecting a speech database to augment the translation by playing a recording of the translated phrase when it is displayed.
